#### Abstract

Let $S$ be a $\chi^{\prime}$-set of $G$. A subset $T \subseteq S$ is said to be a forcing subset for $S$ if $S$ is the unique $\chi^{\prime}$-set containing $T$. The forcing edge chromatic number $f_{\chi^{\prime}}(S)$ of $S$ in $G$ is the minimum cardinality of a forcing subset for $S$. The forcing edge chromatic number $f_{\chi^{\prime}}(G)$ of $G$ is the smallest forcing number of all $\chi^{\prime}$-sets of $G$. In this article, some general properties satisfied by this concept are studied and the forcing edge chromatic number of some standard graphs are determined. Also, connected graphs of order $\mathrm{n} \geq 2$ edge chromatic number 0 or 1 or $\chi^{\prime}(\mathrm{G})$ are characterized. It is shown that for a positive integer a $\geq 2$, there exists a connected graph $G$ such that $\mathrm{f}_{\chi^{\prime}}(\mathrm{G})=\chi^{\prime}(\mathrm{G})=\mathrm{a}$.

Keywords: Forcing edge chromatic number, Edge chromatic number, Chromatic number. AMS Subject Classification: 05C15.

## 1. Introduction

By a graph $G=(V, E)$, we mean a finite, undirected connected graph without loops or multiple edges. The order and size of $G$ are denoted by $n$ and $m$ respectively. For basic graph theoretic terminology, we refer to [1]. Two vertices $u$ and $v$ are said to be adjacent if $u v$ is an edge of $G$. Two edges of $G$ are said to be adjacent if they have a common vertex.

A $k$-coloring of $G$ is a function $c: V(G) \rightarrow\{1,2, \ldots, k\}$, where $c(u) \neq c(v)$ for any two adjacent vertices $u$ and $v$ in $G$. A $p$-vertex coloring of $G$ is an assignment of $p$ colors, $1,2, \ldots p$ to the vertices of $G$, the coloring is proper if no two distinct adjacent vertices have the same color. The minimum colours needed to colour the vertices of $G$ is called chromatic number of $G$, denoted by $\chi(G)$.If $\chi(G)=p, G$ is said to be $p$-chromatic, where $p \leq k$. A set $C \subseteq V(G)$ is called chromatic set if $C$ contains all vertices of distinct colors in $G$. The chromatic number of $G$ is the minimum cardinality among all the chromatic sets of $G$. That is $\chi(G)=\min \left\{\left|C_{i}\right| / C_{i}\right.$ is a chromatic set of $\left.G\right\}$. The concept of the chromatic number was studied in [2,3,4]. A $k$-edge coloring of $G$ is a function $c^{\prime}: E(G) \rightarrow\{1,2, \ldots, k\}$, where $c^{\prime}(e) \neq c^{\prime}(f)$ for any two adjacent edges $e$ and $f$ in $G$. A $p$-edge coloring of $G$ is an assignment of $p$ colors, $1,2, \ldots p$ to the edges of $G$, the coloring is proper if no two distinct adjacent edges have the same color. The minimum colours needed to colour the edges of $G$ is called edge chromatic number of $G$, denoted by $\chi^{\prime}(G)$.If $\chi^{\prime}(G)=p, G$ is said to be $p$-edge chromatic, where $p \leq k$. A set $C^{\prime} \subseteq E(G)$ is called edge chromatic set if $C^{\prime}$ contains all
edges of distinct colors in $G$. The egde chromatic number of $G$ is the minimum cardinality among all the edge chromatic sets of $G$. That is $\chi^{\prime}(G)=\min \left\{\left|C_{i}^{\prime}\right| / C_{i}^{\prime}\right.$ is a edge chromatic set of $G\}$. An edge chromatic set of cardinality $\chi^{\prime}(G)$ is called a $\chi^{\prime}$-set of $G$. The edgechromatic number $\chi^{\prime}(G)$ of $G$ is defined to be the least number of colours needed to colour the edges of $G$ in such a way that no two adjacent edges have the same colour. The concept of the edge chromatic number was studied in [5,6,7]. The chromatic number has application in Time Table Scheduling, Map coloring, channel assignment problem in radio technology, town planning, GSM mobile phone networks etc.[8,9].

## 2. The forcing edge chromatic number of some standard graphs

Definition 2.1. Let $S$ be a $\chi^{\prime}$-set of $G$. A subset $T \subseteq S$ is said to be a forcing subset forSif $S$ is the unique $\chi^{\prime}$-set containing $T$. The forcing edge chromatic number $f_{\chi^{\prime}}(S)$ of $\operatorname{Sin} G$ is the minimum cardinality of a forcing subset for $S$. The forcing edge chromatic number $f_{\chi^{\prime}}(G)$ of $G$ is the smallest forcing number of all $\chi^{\prime}$-sets of $G$.
Example 2.2. For the graph $G$ given in Figure 2.1, $S_{1}=\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}, S_{2}=\left\{e_{6}, e_{2}, e_{3}, e_{4}\right\}$, $S_{3}=\left\{e_{1}, e_{5}, e_{3}, e_{4}\right\}, S_{4}=\left\{e_{6}, e_{5}, e_{3}, e_{4}\right\}$ are the only two $\chi^{\prime}$-sets of $G$ such that $\chi^{\prime}(G)=$ $3, f_{\chi^{\prime}}\left(S_{1}\right)=f_{\chi^{\prime}}\left(S_{2}\right)=f_{\chi^{\prime}}\left(S_{3}\right)=f_{\chi^{\prime}}\left(S_{4}\right)=2$ so that $f_{\chi^{\prime}}(G)=2$.

Figure 2.1

The following result follows immediately from the definitions of the edge chromatic number and the forcing edge chromatic number of a connected graph $G$.
Observation 2.3. For every connected graph $G, 0 \leq f_{\chi^{\prime}}(G) \leq \chi^{\prime}(G)$.
Remark 2.4. The bounds in the Observation 2.3 are sharp. For the complete graph $G=K_{3}, S=E(G)$ is the unique $\chi^{\prime}$-set of $G$ so that $f_{\chi^{\prime}}(G)=0$. For the graph $G$ given in Figure 2.2, $S_{1}=\left\{e_{1}, e_{2}, e_{3}\right\}, S_{2}=\left\{e_{1}, e_{4}, e_{5}\right\}, S_{3}=\left\{e_{1}, e_{2}, e_{6}\right\}, S_{4}=\left\{e_{1}, e_{4}, e_{6}\right\}, S_{5}=$ $\left\{e_{3}, e_{2}, e_{5}\right\}, S_{6}=\left\{e_{3}, e_{4}, e_{5}\right\}, S_{7}=\left\{e_{3}, e_{2}, e_{6}\right\}, S_{8}=\left\{e_{3}, e_{4}, e_{6}\right\}$ such that $f_{\chi^{\prime}}\left(S_{i}\right)=3$ for $i=1$
to 8 and $\chi^{\prime}(G)=3$ so that $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)=3$. Also the bounds are strict. For the graph in Figure 2.1, $\chi^{\prime}(G)=4, f_{\chi^{\prime}}(G)=2$. Thus $0<f_{\chi^{\prime}}(G)<\chi^{\prime}(G)$.

Figure 2.2
Definition: 2.5. An edge $e$ of a graph $G$ is said to be an edge chromatic edge of $G$ if $e$ belongs to every $\chi^{\prime}$-set of $G$.

Example 2.6. For the graph $G$ given in Figure 2.3, $S_{1}=\left\{e_{1}, e_{2}, e_{3}\right\}, S_{2}=\left\{e_{1}, e_{2}, e_{4}\right\}, S_{3}=$ $\left\{e_{5}, e_{2}, e_{3}\right\}, S_{4}=\left\{e_{5}, e_{2}, e_{4}\right\}$ are the only $\chi^{\prime}$-sets of $G$ such that $e_{2}$ is a chromatic edge of $G$.

G
Figure 2.3

Theorem 2.7. Let $G$ be a connected graph of order $n \geq 2$ with $\Delta(G)=n-1$. Let $x$ be auniversal vertex of $G$ and $e$ be an edge incident with $x$. Then $e$ is a chromatic edge of $G$.

Proof. On the contrary, suppose that $e$ is not a chromatic edge of $G$. Then there exists a $\chi^{\prime}$-set $S$ of $G$ such thate $=u v$. Let $c(e)=c_{1}$. Since $e \notin S$, there exists $f=y z \in E(G)$ such that $c(f)=c_{1}$ and $y \neq x, v$ and $z \neq x, v$. Hence it follows that $x$ is not a universal vertex of $G$, which is a contradiction. Therefore $e$ is a chromatic edge of $G$.

Theorem 2.8. Let $G$ be a connected graph. Then
(a) $f_{\chi^{\prime}}(G)=0$ if and only if $G$ has a unique $\chi^{\prime}$-set.
(b) $f_{\chi^{\prime}}(G)=1$ if and only if $G$ has at least two $\chi^{\prime}$-sets, one of which is a
unique $\chi^{\prime}$-set containing one of its elements, and
(c) $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)$ if and only if no $\chi^{\prime}$-set of $G$ is the unique $\chi^{\prime}$-set containing any of its proper subsets.

Proof. (a) Let $f_{\chi^{\prime}}(G)=0$. Then, by definition, $f_{\chi^{\prime}}(S)=0$ for some $\chi^{\prime}$-set $S$ of $G$ so that the empty set $\phi$ is the minimum forcing subset for $S$. Since the empty set $\phi$ is a subset of every set, it follows that $S$ is the unique $\chi^{\prime}$-set of $G$. The converse is clear.
(b) Let $f_{\chi^{\prime}}(G)=1$. Then by Theorem 2.8(a), $G$ has at least two $\chi^{\prime}$-sets. Also, since $f_{\chi^{\prime}}(G)=1$, there is a singleton subset $T$ of a $\chi^{\prime}$-set $S$ of $G$ such that $T$ is not a subset of any other $\chi^{\prime}$-set of $G$. Thus $S$ is the unique $\chi^{\prime}$-set containing one of its elements. The converse is clear.
(c) Let $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)$. Then $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)$ for every $\chi^{\prime}$-set $S$ in $G$. Also, by

Observation 2.3, $\chi^{\prime}(G) \geq 2$ and hence $f_{\chi^{\prime}}(G) \geq 2$. Then by Theorem 2.8(a), $G$ has at least two $\chi^{\prime}$-sets and so the empty set $\phi$ is not a forcing subset for any $\chi^{\prime}$-set of $G$. Since $f_{\chi^{\prime}}(S)=\chi^{\prime}(G)$, no proper subset of $S$ is a forcing subset of $S$. Thus no $\chi^{\prime}$-set of $G$ is the unique $\chi^{\prime}$-set containing any of its proper subsets. Conversely, the data implies that $G$ contains more than one $\chi^{\prime}$-set and no subset of any $\chi^{\prime}$-set $S$ other than $S$ is a forcing subset for $S$. Hence it follows that $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)$.
Theorem 2.9. Let $G$ be a connected graph and $W$ be the set of all chromaticedges of $G$. Then $f_{\chi^{\prime}}(G) \leq \chi^{\prime}(G)-|W|$.
Proof. Let $S$ be any $\chi^{\prime}$-set of $G$. Then $\chi^{\prime}(G)=|S|, W \subseteq S$ and $S$ is the unique $\chi^{\prime}$-set containing $S-W$. Thus $f_{\chi^{\prime}}(G) \leq|S-W|=|S|-|W|=\chi^{\prime}(G)-|W|$.
In the following we determine the forcing edge chromatic number of some standard graphs.
Theorem 2.10. For the complete graph $G=K_{n}(n \geq 2)$,
$f_{\chi^{\prime}}(G)=\left\{\begin{array}{l}0 \quad \text { if } n=2,3 \\ 3 \text { if } n=4 \\ n-1 \text { if } n \geq 5\end{array}\right.$
Proof. For $n=2$ and $n=3, S=E(G)$ is the unique $\chi^{\prime}$-set of $G$, the result follows from Theorem 2.8 (a). For $n=4$, let $e_{11}=v_{1} v_{2}, e_{12}=v_{1} v_{3}, e_{13}=v_{1} v_{4}, e_{21}=v_{2} v_{3}, e_{22}=$ $v_{2} v_{4}, \quad e_{31}=v_{3} v_{4} . \quad$ Assign $\quad c^{\prime}\left(e_{11}\right)=c^{\prime}\left(e_{31}\right)=1, c^{\prime}\left(e_{12}\right)=c^{\prime}\left(e_{22}\right)=2, c^{\prime}\left(e_{13}\right)=$ $c^{\prime}\left(e_{21}\right)=3$. Then $S_{1}=\left\{e_{11}, e_{12}, e_{13}\right\}, S_{2}=\left\{e_{11}, e_{12}, e_{21}\right\}, S_{3}=\left\{e_{11}, e_{22}, e_{13}\right\}, S_{4}=$ $\left\{e_{11}, e_{22}, e_{21}\right\}, S_{5}=\left\{e_{31}, e_{12}, e_{13}\right\}, S_{6}=\left\{e_{31}, e_{12}, e_{21}\right\}, S_{7}=\left\{e_{31}, e_{22}, e_{13}\right\}, \quad S_{8}=$
$\left\{e_{31}, e_{22}, e_{21}\right\}$ are the $\chi^{\prime}$-set of $G$ such that $f_{\chi^{\prime}}\left(S_{i}\right)=3$ for $i=1$ to 8 so that $f_{\chi^{\prime}}(G)=3$. For $n \geq 5$, let $e_{1 j}=v_{1} v_{j}(2 \leq j \leq n), e_{2 j}=v_{2} v_{j}(3 \leq j \leq n), e_{3 j}=v_{3} v_{j}(4 \leq j \leq n)$, $\ldots, e_{(n-1) j}=v_{n-1} v_{n}$. Assign $\quad c^{\prime}\left(e_{1 j}\right)=c_{j}^{\prime}, c^{\prime}\left(e_{2 j}\right)=c_{j}^{\prime}-1(1 \leq j \leq n-1), \quad c^{\prime}\left(e_{3 j}\right)=$ $c_{j}^{\prime}-2(1 \leq j \leq n-1), \ldots \ldots \ldots, c^{\prime}\left(e_{(n-1) j}\right)=c_{j}^{\prime}-(n-2)(1 \leq j \leq n-1)$, $c^{\prime}\left(e_{(n-2) j}\right)=n$ so that $\chi^{\prime}(G)=n$. Since $e_{(n-2) j}$ is a chromatic edge of $G$, by Theorem 2.9, $f_{\chi^{\prime}}(G) \leq n-1$. Let $S$ be a chromatic edge set of $G$. We prove that $f_{\chi^{\prime}}(G)=n-1$. On the contrary, suppose that $f_{\chi^{\prime}}(G) \leq n-2$. Then there exists a forcing subset $T$ of $S$ such that $|T| \leq n-2$. Let $e \in S$ such that $e \notin T$. Then $e$ is not a chromatic edge of $G$. Without loss of generality, let us assume that $c^{\prime}(e)=c_{1}^{\prime}$. Since $n \geq 5$, there exists $f \in E(G)$ such that $c^{\prime}(f)=c_{1}^{\prime}$. Let $S^{\prime}=[S-\{e\}] \cup\{f\}$. Then $S^{\prime}$ is a $\chi^{\prime}$-set of $G$. Hence $T$ is a proper subset of a $\chi^{\prime}$-set $S^{\prime}$ of $G$, which is a contradiction. Therefore $f_{\chi^{\prime}}(G)=n-1$.

Theorem 2.11. For the star graph $G=K_{1, n-1}(n \geq 3), f_{\chi^{\prime}}(G)=1$.
Proof. Since $S=E(G)$ is the unique $\chi^{\prime}$-set of $G$, the result follows from Theorem 2.8(a) Theorem 2.12. For the double star graph $G=K_{2, r, s}, f_{\chi^{\prime}}(G)=2$.
Proof. Let $V=\left\{x, v_{1}, v_{2}, \ldots, v_{r}\right\} \cup\left\{y, u_{1}, u_{2}, \ldots, u_{s}\right\}$ be the vertex set of $G$. Let $f_{i}=x v_{i}, e=$ $x y, g_{i}=y u_{j}$ be the edge set of $G$ for all $(1 \leq i \leq r)$ and ( $\left.1 \leq j \leq s\right)$ where $r+s=n-$ 2. Then $S_{1}=\left\{e, f_{i}\right\}(1 \leq i \leq r)$ and $S_{2}=\left\{e, g_{j}\right\}(1 \leq j \leq s)$ are the only $\chi^{\prime}$-sets of $G$ such that $f_{\chi^{\prime}}\left(S_{1}\right)=f_{\chi^{\prime}}\left(S_{2}\right)=2$ so that $f_{\chi^{\prime}}(G)=2$.

Theorem 2.13. For the complete bipartite graph $G=K_{r, s}(1 \leq r \leq s)$,
$f_{\chi^{\prime}}(G)=\left\{\begin{array}{lc}0 & \text { if } r=1, s=1 \\ 2 & \text { if } r=2, s=2 \\ s & \text { if } 2 \leq r \leq s\end{array}\right.$
Proof. For $r=1$ and $s \geq 2$, then the result follows from Theorem 2.11. For $r=2$ and $s=2$, $S_{1}=\left\{e_{11}, e_{12}\right\}, S_{2}=\left\{e_{11}, e_{21}\right\}, S_{3}=\left\{e_{22}, e_{12}\right\}, S_{4}=\left\{e_{22}, e_{21}\right\} \quad$ are the $\chi^{\prime}$-sets of $G$ such that $f_{\chi^{\prime}}\left(S_{i}\right)=2$ for $i=1$ to 4 so that $f_{\chi^{\prime}}(G)=2$. So let $2 \leq r \leq s$. Let $X=$ $\left\{x_{1}, x_{2}, \ldots, x_{r}\right\}$ and $Y=\left\{y_{1}, y_{2}, \ldots, y_{s}\right\}$ be the bipartite sets of $G$.Let $e_{1 j}=x_{1} y_{j}(1 \leq j \leq$ s), $e_{2 j}=x_{2} y_{j}(1 \leq j \leq s), \ldots \ldots \ldots, e_{i j}=x_{i} y_{j}(1 \leq i \leq r)(1 \leq j \leq s)$. Assign $c^{\prime}\left(e_{1 j}\right)=$ $c_{j}^{\prime}(1 \leq j \leq s), c^{\prime}\left(e_{2 j}\right)=c_{j}^{\prime}, c_{1}^{\prime}(2 \leq j \leq s), c^{\prime}\left(e_{3 j}\right)=c_{j}^{\prime}, c_{1}^{\prime}, c_{2}^{\prime}(3 \leq j \leq), \ldots \ldots \ldots, c^{\prime}\left(e_{i j}\right)=$ $c_{s}^{\prime}, c_{1}^{\prime}, c_{2}^{\prime}, \ldots \ldots \ldots, c_{s-1}^{\prime}(1 \leq i \leq r)(1 \leq j \leq s)$. Then $S_{i j}=\left\{e_{11}, e_{12}, e_{13}, \ldots, e_{k s}\right\}$ is a $\chi^{\prime}$-set of $G$ such that $\chi^{\prime}(G)=s$. By Observation $2.3,0 \leq f_{\chi^{\prime}}(G) \leq s$. Since $\chi^{\prime}$-set of $G$ is not unique $f_{\chi^{\prime}}(G) \geq 1$. It is easily observed that no singleton subsets or two element subsets of
$S_{i j}(1 \leq i \leq r),(1 \leq j \leq s)$ is not a forcing subset of $S_{i j}$ so that $f_{\chi^{\prime}}\left(S_{i j}\right)=s$. Since this true for all $\chi^{\prime}$-set $S_{i j}(1 \leq i \leq r),(1 \leq j \leq s)$ so that $f_{\chi^{\prime}}(G)=s$.
Theorem 2.14. For the path $G=P_{n}(n \geq 3), f_{\chi^{\prime}}(G)= \begin{cases}0 & \text { if } n=3 \\ 1 & \text { if } n=4 \\ 2 & \text { if } n \geq 5\end{cases}$
Proof. Let $P_{n}$ be $v_{1}, v_{2}, \ldots, v_{n}$ and let $e_{i}=v_{i} v_{i+1}(1 \leq i \leq n-1)$. For $n=3$, $S=E(G)$ is the unique $\chi^{\prime}$-set of $G$, the result follows from Theorem 2.8(a). For $n=4, S_{1}=\left\{e_{1}, e_{2}\right\}$ and $S_{2}=\left\{e_{2}, e_{3}\right\}$ are the $\chi^{\prime}$-sets of $G$ such that $f_{\chi^{\prime}}\left(S_{1}\right)=$ $f_{\chi^{\prime}}\left(S_{2}\right)=1$ so that $f_{\chi^{\prime}}(G)=1$. So let $n \geq 5$. Then $S_{i}=\left\{e_{i}, e_{i+1}\right\}(1 \leq i \leq n-1)$ and $S_{j k}=\left\{e_{j}, e_{k}\right\}(1 \leq j \leq k \leq n-1)$ and $|j-k|$ is odd are the only $\chi^{\prime}$-sets of $G$ such that $f_{\chi^{\prime}}\left(S_{i}\right)=2$ for $(1 \leq i \leq n-1)$ and $f_{\chi^{\prime}}\left(S_{j k}\right)=2$ for $(1 \leq j \leq k \leq n-$ 1) so that $f_{\chi^{\prime}}(G)=2$.

Theorem 2.15. For the cycle $G=C_{n}(n \geq 4), f_{\chi^{\prime}}(G)=2$.
Proof. Let $C_{n}$ be $v_{1}, v_{2}, \ldots, v_{n}, v_{1}$ and let $e_{i}=v_{i} v_{i+1}(1 \leq i \leq n-1)$ and $e_{n}=v_{n} v_{1}$.
We consider the following two cases.
Case(1) $n$ is even

$$
c\left(e_{i}\right)=\left\{\begin{array}{l}
1, \text { if } i \text { is odd } \\
2, \text { if } i \text { is even }
\end{array}\right.
$$

Then $S_{i}=\left\{e_{i}, e_{i+1}\right\}(1 \leq i \leq n-1)$ and $S_{i j k}=\left\{e_{j}, e_{k}\right\}(1 \leq j \leq k \leq n-1)$ and $|j-k|$ is odd are the only $\chi^{\prime}$-sets of $G$ such that $f_{\chi^{\prime}}\left(S_{i}\right)=2$ and $f_{\chi^{\prime}}\left(S_{j k}\right)=2$ for $(1 \leq i \leq n-1)$ and $(1 \leq j \leq k \leq n-1)$ so that $f_{\chi^{\prime}}(G)=2$.
Case(2) $n$ is odd

$$
c\left(e_{i}\right)=\left\{\begin{array}{l}
1 \text { if } n \text { is odd } \\
2 \text { if } n \text { is even } \\
3 \quad \text { if } i=n
\end{array}\right.
$$

Since $E\left(v_{n} v_{1}\right)$ is the set of chromatic edges of $G, E\left(v_{n} v_{1}\right)$ is a subset of every $\chi^{\prime}$-set of $G$. It can be easily seen that any $\chi^{\prime}$-set of $G$ is of the form $S=E\left(v_{n} v_{1}\right) \cup\{x, y\}$, where $x, y \in$ $\left\{e_{1}, e_{2}, \ldots, e_{n-1}\right\}$ so that $\chi^{\prime}(G)=n+2$. By Theorem 2.9, $f_{\chi^{\prime}}(G) \leq n+2-n=2$. Since $\chi^{\prime}$ set of $G$ is not unique $f_{\chi^{\prime}}(G) \geq 1$. It is easily observed that no singleton subsets of $S$ is not a forcing subset of $S$ so that $f_{\chi^{\prime}}(S)=2$. Since this is true for all $\chi^{\prime}$-set $S$ of $G, f_{\chi^{\prime}}(G)=2$. Theorem 2.16. For a positive integer $a \geq 2$, there exists a connected graph $G$ such that $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)=a$.
Proof. For $a=2$, let $G=C_{4}$. Then by Theorem 2.15, $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)=a$. So, let
$a \geq 3$. Let $G=K_{2, a}$. By Theorem 2.13, $f_{\chi^{\prime}}(G)=\chi^{\prime}(G)=a$.

## 3. Conclusion

In this article, we discuss about a new concept namely, forcing edge chromatic number of a graph. Also, the relation between edge chromatic number and forcing edge chromatic number is found. The above concept is examined by some standard graphs with examples.
